RECORD 10

THE DESYNCED MARKETPLACE APPEALS LOOP

Technical Environment System Review | Documented by Hamgram77 | October 17, 2026

Executive summary: This record analyzes a reported post-appeal failure mode in which a moderation decision is reversed but one or more downstream marketplace systems continue treating the asset as restricted. The resulting state can show an asset as approved in a creator-facing dashboard while the public catalog, search index, sale state, or support record remains stale.

1. SYSTEM SCOPE

A marketplace asset can be represented in multiple services at once. An appeal reversal must propagate consistently across moderation records, asset metadata, catalog visibility, commerce eligibility, search indexing, creator dashboards, and support case history. This record calls a mismatch between those surfaces a desync event.

- The model applies to UGC, clothing, and other marketplace assets where moderation and commerce state intersect.
- It does not assume a particular internal database design; the service boundaries below are an analytical model based on observable states.

2. THE APPEAL-TO-CATALOG STATE CHAIN

State surface	Expected state after a successful appeal	Desync symptom
Moderation decision	Restriction reversed and decision history updated.	Appeal shows successful but dependent systems still read the old flag.
Asset record	Asset eligibility and moderation fields agree.	Dashboard says approved while a hidden restriction remains.
Catalog and search	Item can be discovered when all ordinary sale rules are met.	Direct dashboard access works, but buyers cannot find or view the item.
Commerce state	Sale and ownership functions follow the cleared asset state.	Item remains off sale or purchase calls fail despite approval.
Support history	Case remains reopenable if propagation fails.	New tickets close as duplicates because the appeal itself is marked resolved.
Financial ledger	Fees and any remediation decision are recorded clearly.	Upload cost remains charged with no usable asset or reconciliation path.

3. ANALYSIS OF THE GLITCH ENGINE

3.1 The desync event

A human reversal can update the account-level moderation record without completing every downstream asset update. If an event is dropped, delayed, rejected, or processed out of order, a stale catalog restriction can survive after the source decision changes.

3.2 Dashboard dead-ends

A creator dashboard may read from a newer or different state store than the public catalog. The creator sees 'Approved,' but discovery or purchase systems still receive the old eligibility value. A support macro that checks only the closed appeal record can then conclude that no work remains.

3.3 Financial asset forfeiture risk

When an upload fee remains charged but the cleared asset cannot be listed, the creator absorbs the cost of a platform-state failure. Even if the amount is small per asset, repeated failures can compound across a catalog and affect independent sellers disproportionately.

3.4 Operational opacity

Without a visible propagation status, creators cannot determine whether they should wait, republish, contact support, or avoid changing the asset. Re-uploading may create duplicate costs or a second moderation event rather than repairing the original record.

4. DIAGNOSTIC INDICATORS

- The appeal decision and creator dashboard show approval, but the public item URL remains unavailable or restricted.
- The item is absent from catalog search, group inventory, storefront collections, or expected discovery surfaces.
- Sale controls appear enabled in one interface but buyers receive an unavailable or non-purchasable state.
- A new ticket is closed as resolved or duplicate without checking the catalog and commerce states.
- The behavior persists beyond the stated processing window and across a signed-out or separate test session.

5. EVIDENCE AND SAFE REPRODUCTION PLAN

Creators should document the mismatch without publishing private account information or encouraging repeated purchases.

- Record the asset identifier, asset type, appeal decision date, and the exact status shown in each creator-facing interface.
- Capture the public catalog result from a signed-out browser or separate test account, where permitted.
- List the first observed failure time, later retest times, and whether search, direct URL, and purchase state differ.
- Reference the prior appeal ticket and ask support to investigate post-appeal propagation rather than reconsider the already-reversed decision.
- Retain proof of the upload fee and any duplicate charge, but submit financial records only through official authenticated channels.

6. CONTROL AND RECOVERY DESIGN

Control	Purpose	Success condition
Automated reconciliation job	Compare the final appeal decision with asset, catalog, search, and commerce states.	Every dependent state reaches the approved version or produces an actionable error.
Creator-visible sync status	Show pending, complete, or failed propagation after an appeal.	The creator can distinguish normal delay from a broken state.
Force-sync request	Allow a safe, rate-limited reprocessing request without remoderating content.	The original decision is replayed and logged across dependent services.
Ticket reopen route	Prevent duplicate-ticket automation from hiding a propagation fault.	A closed appeal can spawn a linked technical incident.
Fee reconciliation	Review charges when an approved asset remains unusable because of platform error.	Refund, credit, or written denial is attached to the incident record.

7. PROPOSED FORCE-SYNC SAFEGUARDS

- Require a final successful appeal state before the control becomes available.
- Make the action idempotent so repeated clicks cannot create conflicting asset versions or duplicate fees.
- Display the services checked, the last sync time, and a stable incident reference when any service fails.
- Rate-limit requests and preserve a full audit trail for support and engineering review.

8. RESOLUTION ACCEPTANCE CRITERIA

A post-appeal case is complete only when the moderation record, creator dashboard, public catalog, search visibility, sale eligibility, and financial disposition are mutually consistent. Closing the appeal ticket alone is not sufficient evidence of technical recovery.

9. CONCLUSION

Appeal reversals must behave like durable state changes, not isolated support events. Cross-service reconciliation, visible sync status, a linked technical escalation route, and fee review would convert an opaque loop into a testable recovery process.

DOCUMENT STATUS: This record is an independent analytical brief. It documents reported risks and a proposed system model; it does not claim access to Roblox's private infrastructure, internal support tooling, or confidential decision criteria.
